- Corpus-based query expansion
- Pseudo-relevance feedback
- Discussion

### Lab 5: Retrieval models

- Documents ranking with Lucene’s retrieval models
- Vector Space Model (Cosine TF-IDF)
- Best Model 25 (BM25)
- Language Model with Dirichlet Smoothing (LMD)
- Discussion
- Advanced discussion

### Lab 6: Indexing multiple fields

- Creating a large set of indexing fields
- PerField processing
- Query processing
- Discussion

### Lab 7: Rank fusion and learning to rank

- Searching with multiple fields
- Unsupervised rank fusion
- Learning-to-rank (LETOR)
- Discussion

### Lab 8: PageRank for the StackOverflow Social-Graph

- StackOverflow social-graph
- PageRank
- PageRank with weighted links
- Re-rank search results
- Discussion

### Exercises

- Exercises
Course Syllabus
The goal of this hands-on course is to provide students with an understanding of all aspects of the design and implementation of Web search engines. Students will master the fundamental concepts of Information Retrieval, i.e., text representation, indexing, querying, and ranking by relevance.

Learning outcomes
Knowledge:

- Learn the concept of information relevance.
- Analyse Web and multimedia data.
- Learn how to rank information by relevance.
- Understand evaluation protocols.

Know-how:

- Implement information retrieval models.
- Ability to adapt and improve components of a search engine.
- Deploy search engines with large-scale datasets.
- Design evaluation protocols and evaluate search engines.

Soft-Skills:

- Select the right IR techniques for particular problems.
- Design information retrieval systems.
- Ability to do critical thinking about retrieval results.

Organization
During the course lectures, we will discuss key concepts and introduce well-established information retrieval techniques and algorithms: the vector space model, the BM25 retrieval model, information relevance, PageRank, indexing, language models and learning to rank.

Students are further exposed to these key information retrieval concepts on the laboratory lectures. The weekly laboratories, aim to provide students with a hands-on experience to allow the consolidation of the concepts discussed in the lectures.

Web Search students (Computer Science M.Sc.) are guided through the first laboratories and later implement a larger project, where the software constructs developed during the guided hands-on laboratory sessions will be applied to solve a real-world problem.

Information Retrieval students (Big Data Analysis and Engineering M.Sc.) are guided through the full set of laboratories, requiring a more careful analysis of experimental results at specific checkpoints throughout the semester.

Pre-requisites:

- Good programming skills (Java and some scripting language)
- Critical analysis skills
Course planning

The weekly plan is presented on the following table.

<table>
<thead>
<tr>

Bibliography

Hands-on Information Retrieval and Web search

Goals
You will understand the following aspects of a search engine:

- Text pre-processing: tokenization, stop words, stemming, n-grams.
- Indexing fields and document ranking by relevance.
- Retrieval models.
- Rank fusion and learning to rank.
- Ranking by document authority.
- Search engine evaluation methods.

Case study project: Searching StackOverflow Q&A
In this case study, you will be guided through a number of steps to implement a search system for the StackOverflow CrossValidated Answers dataset. Your system should be able to:

1. Accept search queries from the command line;
2. Parse the search queries correctly;
3. Submit the search queries to the search engine;
4. Produce the search results in a specified file format.

The search system will be implemented incrementally, each week adding a new component.

Software requisites
The search index must be supported by Lucene (although, there are other more research oriented search engines). The project implementation can be in either Java (better search engine support) or Python (better text pre-processing support).

Lucene
Lucene is a search engine library that provides fundamental search algorithms and text processing methods to build text search engines. Download the Lucene library (https://lucene.apache.org/) and create an Eclipse project with the following Lucene jars (you can use Maven):

Libraries: core.jar analyzers-common.jar queries.jar queryparser.jar

There are other libraries external to Lucene that you may wish to use. However, it is strongly advisable to focus your efforts in studying and understanding the fundamentals of the search and indexing algorithms provided by Lucene.

Luke
To test and inspect the index you can use Luke. Luke is a “development and diagnostic tool, which accesses already existing Lucene indexes and allows you to display and modify their content in several ways”. Download the jar file (https://github.com/DmitryKey/luke/releases) and run it in your local machine to inspect Lucene indexes and test search queries. Please, make sure you download a version of Luke that is compatible with your version of Lucene.

RankLib
RankLib is a library part of the LEMUR search engine, that implements several learning-to-rank algorithms.
JSoup

Jsoup is a library to parse and extract text from HTML documents. It can be extremely useful to clean HTML tags and other Web specific strings from your documents before indexing them.
Lab 1: Introduction to Lucene

In this first laboratory, you will get familiar with the basics of the text search framework Apache Lucene. A baseline java implementation of a search engine to index text documents and search the text index is available on CLIP. You must create a project with this sample code, correct existing errors and adapt it to solve this guide.

The goal of the search system, to be implemented throughout these hands-on labs, is to find the best answer to each question using only search algorithms. In this approach, you should index only the answers.

Dataset

From the lab materials Web page (http://ctp.di.fct.unl.pt/~jmag/ws/materials.html) download the dataset of questions and answers from The StackOverflow CrossValidated forum. The dataset is organized as follows:

- **Answers.csv** - contains a list of answers. Each answer is organized into the following fields:
  - Id - identifier of the question/answer.
  - OwnerUserId - identifier of the author of this question/answer.
  - CreationDate - date of this question/answer.
  - ParentId - identifier of the parent question/answer.
  - Score - the score given by the user community.
  - Body - the body text of the question.

- **Questions.csv** - contains a list of questions. Each question is organized into the following fields:
  - Id - identifier of the question/answer.
  - OwnerUserId - identifier of the author of this question/answer.
  - CreationDate - date of this question/answer.
  - Score - the score given by the user community.
  - Title - the title text of the question.
  - Body - the body text of the question.

- **queries.offline.txt** - a set of queries to run offline evaluations. The format is `queryId:queryString`.
- **qrels.offline.txt** - the trec_eval groundtruth to perform offline evaluations.

Each question and answer have their own Id, which will be used to evaluate your search results. There are other fields that you may wish to consider in your implementation.

The code to parse the *.csv files are provided with the Eclipse project.

Building and searching the index

When you create an index with Lucene with the **IndexWriter** class, you need to specify the **Analyzer** class that will analyse your text documents and the **Similarity** class that will compare your query to the documents in the index.

In Lucene **Documents** are composed of **Fields**. In contrast to SQL databases, Lucene allows you to index data without storing it. Searches are always done on the fields. Make sure you read and understand the documentation related to these core classes.
To search the index, you also need to specify an Analyzer class that will now analyse the query text and the Similarity class to compare queries to the documents in the index. The IndexSearch class provides several useful methods:

- The search method receives a query and returns a ranked list of documents from the index. Each document has a similarity score that quantifies the similarity between the document and the query.
- The searcher method explain also allows you understand numerical calculation of the similarity between a query and a document.

**Evaluation**

Offline evaluation is done with the trec_eval command line application. From the lab materials Web page (http://ctp.di.fct.unl.pt/~jmag/ws/materials.html) you can download its Windows binary or the Linux source code and build it on local machine. To print the evaluation report of your system, you need to run trec_eval from the command line as follows:

```
./trec_eval qrels.txt myresults.txt
```

Your software must write search results in a file format that enables trec_eval to produce evaluation reports. trec_eval expects its input to be in the format described below.

```
QueryID   Q0  DocID    Rank  Score  RunID
10        Q0  43254353  1     16.2  run-1
10        Q0  0987687462  3    9.1   run-1
:         :   :        :    :     :
11        Q0  2652542  1     18.1  run-1
```

The QueryID should correspond to the query ID of the query you are evaluating. Q0 is a required constant that you can ignore. The DocID should be the external document ID. trec_eval does not use the rank field to sort results, therefore the scores should be in descending order, to indicate that your results are ranked. The Run ID is an experiment identifier which can be set to anything.

**Data workflow**

Understand the data workflow and draw a diagram depicting the data processing elements that you identify in the code.
Understanding search results
Based on the search results, inspect the search results using the *explain method* of the search framework. Describe the general structure of this output.

Based on the TF-IDF with cosine distance retrieval mode, discuss the output of the *explain method* of the Lucene framework.

Modify the provided code to read the queries from the file “queries.offline.txt” and produce the “results.txt” file according to the trec_eval format. Run the command line application trec_eval to evaluate your search engine. What is your precision after 10 retrieved documents?

Using a spreadsheet, plot the precision at different rank positions (P5, P10, P15, P20, P30, P50,...) and discuss what you observe.
Lab 2: Text pre-processing

Lucene is a full-text index system\(^1\). As such, it implements an extensive text analysis API\(^2\) with several algorithms to analyse text from different languages and domains. The goal of the text pre-processing and analysis steps is to generate tokens, the minimal set of characters extracted from sentences that will be indexed internally.

Analyzers

Natural language is a rich form of representing knowledge. Most search engines take a pragmatic approach to textual information and seek for the most low-level, but relevant, patterns existing in text. Lucene follows this approach and processes text in a pipeline fashion, processing each word at a time. Lucene Analyzer classes are used to analyse text and produce the tokens to be used by the indexing or search tasks. When a document is indexed or a query is parsed, an Analyser is invoked through the `createComponents` method that returns a chain of TokenFilters that generate the final tokens from the original text.

```java
Analyzer analyzer = new Analyzer() {
    @Override
    protected TokenStreamComponents createComponents(String fieldName) {
        Tokenizer source = new FooTokenizer(reader);
        TokenStream filter = new FooFilter(source);
        filter = new BarFilter(filter);
        return new TokenStreamComponents(source, filter);
    }
}
```

Text based Token filters

Study the code made available on CLIP and the course lecture about fundamental text pre-processing techniques. These techniques are implemented as TokenFilters and can be used in chain to strip text out of its irrelevant elements and reduce it to its canonical linguistic patterns.

Using the provided code understand how the different token filters generate different tokens: *punctuation removal, stop words, word-grams, n-grams, stemming*.

HTML Token filters

Pure text indexes, are designed to handle text only data. To handle structured documents, they must be decomposed into text segments, that are then indexed separately or without the structural information (e.g. html tags).

Lucene provides a simple HTML parser that removes tags from a stream. The HTMLCharFilter class wraps a reader class and removes the HTML tags from that stream.

```java
Analyzer analyzer = new Analyzer() {
    @Override
    protected TokenStreamComponents createComponents(String fieldName) {
        Tokenizer source = new FooTokenizer(reader);
        TokenStream filter = new FooFilter(source);
        return new TokenStreamComponents(source, filter) {
            @Override
            protected void setReader(final Reader reader) {
                super.setReader(new HTMLStripCharFilter(reader));
            }
        };
    }
}
```

---

\(^1\) Support for complex document formats, such as PDF, Word, XML and ODF, is provided by the [Apache Tika library](http).

\(^2\) Support for multiple languages, dictionaries, Wikipedia, HTML, etc. can be found on the [analysis-common API](http).
Other more complete HTML parsers exist such as Boilerpipe and Jsoup. You can use one of these libraries if you are not happy with the result of Lucene’s HTML pre-processing result.

```java
String html = "<p>An <a href='http://example.com/'>example</a> link.</p>"
Document doc = Jsoup.parse(html);
String text = doc.body().text(); // "An example link"
```

**Fields extraction with regular expressions**

In some cases, your text documents contain specific information that follow a pattern. For example, most of the times, the age of a person is expressed as “75 years old”. In such situations, Lucene’s class PatternReplaceCharFilter enables the implementation regular expressions to extract information that are exist in the documents according to a known text pattern.

**Experiments automation**

This homework requires a large number of experiments. If you use scripts in your favourite language to write parameter files with adjusted parameter settings, most of the experiments will require minimal manual effort, thus most of your effort will be in analysing experimental results. If you try to run all of the experiments manually, it will be very tedious and time-consuming.

We suggest that your script write results in a tabular format (e.g., .csv) similar to what you will need for your report to facilitate analysis.

**Experiment: Stream readers**

Observe the impact of each text reading method on the search results. Provide numerical results that compare the different methods. Fill the table bellow:

<table>
<thead>
<tr>
<th>Readers</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plain reader</td>
<td></td>
</tr>
<tr>
<td>HTMLCharStripFilter</td>
<td></td>
</tr>
<tr>
<td>Jsoup</td>
<td></td>
</tr>
</tbody>
</table>

**Experiment: Tokenizers**

Observe the impact of each text tokenization method on the search results. Provide numerical results that compare the different methods. Fill the table bellow:

<table>
<thead>
<tr>
<th>Tokenizer</th>
<th>Input Sentence: A web search engine is a software system that is designed to search for information on the WWW.</th>
</tr>
</thead>
<tbody>
<tr>
<td>StandardTokenizer</td>
<td></td>
</tr>
<tr>
<td>WhitespaceTokenizer</td>
<td></td>
</tr>
<tr>
<td>UAX29URLEmailTokenizer</td>
<td></td>
</tr>
</tbody>
</table>
**Experiment: Filters**

Observe the impact of each text filtering method on the search results. Provide numerical results that compare the different methods. Fill the table bellow:

<table>
<thead>
<tr>
<th>Tokenizer</th>
<th>Input Sentence: A web search engine is a software system that is designed to search for information on the WWW.</th>
</tr>
</thead>
<tbody>
<tr>
<td>StandardFilter</td>
<td></td>
</tr>
<tr>
<td>LowerCaseFilter</td>
<td></td>
</tr>
<tr>
<td>StopFilter</td>
<td></td>
</tr>
<tr>
<td>SnowballFilter</td>

Lab 3: Evaluation metrics

Evaluating the search results is an important step in the design and implementation of a search engine. The dataset is a key evaluation instrument: it requires query-document relevance judgments, indicating if a document is valid for a given query. In every evaluation, you must consider the types of relevance judgments that you require:

- **Binary relevance judgments**: For each question, an answer is considered to be relevant if it has a score greater than 1/3 of the question score.
- **Multi-level relevance judgments**: For each question, i) an answer is non-relevant (=0) if it has a score lower than 1/3 of the question score; ii) an answer relevant (=1) if it has a score between 1/3 and 2/3 of the question score; and iii) an answer is highly-relevant (=2) if it has a score higher than 2/3 of the question score.

Follow the script provided on CLIP to evaluate your search results. You can only search for answers using the text information and the user PageRank information.

Search utility metrics

**Precision** measures the number of relevant retrieved documents over a total of retrieved documents. A popular measure is Precision at 10 or 30 retrieved documents (first page or first three pages of results).

\[
Precision = \frac{truePos}{truePos + falsePos}
\]

**Recall** measures the number of relevant retrieved documents over the total number of relevant documents (including the ones that are not retrieved). This metric requires that the full set of documents is annotated with relevant or not relevant for every test query.

\[
Recall = \frac{truePos}{truePos + falseNeg}
\]

**Normalized Discount Gain** is useful when some documents are more relevant than others. Documents need to have ground-truth with different levels of relevance:

\[
DCG_m = \sum_{i=1}^{m} \frac{2^{rel_i} - 1}{\log_2(1+i)} \quad rel_i = \{0,1,2,3, \ldots\} \quad nDCG_m = \frac{DCG_m}{bestDCG_m}
\]

**Search stability metrics**

**Precision-recall graphs** provide a detailed view of the complete search results (not just the top). It is important to assess the system stability across the entire rank and a wide range of queries.

**Average precision** is the area under the P-R curve:

\[
AP = \frac{1}{\#relevant} \sum_{k=1}^{\text{set of positions of the relevant docs}} p@k
\]

**Mean average precision** evaluates the system for a given range of queries. It summarizes the global system performance in one single value. It is the mean of the average precision of a set of \(n\) queries:

\[
MAP = \frac{AP(q_1) + AP(q_2) + AP(q_3) + \ldots + AP(q_n)}{n}
\]
Systematic evaluation

Implement a script that generates and compiles all evaluation results into a single file. A second script is then required to parse the evaluation results file and generate all plots and the tables. This will allow you to easily pick the ones that best represent phenomena that you may wish to single-out and analyse.

Discussion

1. Once you have understood all the metrics, merge the results of all your past results. On a table, list the retrieval precision for all queries. Include the average retrieval precision.

2. Plot the precision recall curves for all queries in one single graph. Overlay the average of that curve. Discuss the variation.

3. Analyse and discuss the evaluation results from the perspective of retrieval recall.

4. Compare the MAP metric, the average of P@10 metric and the average of queries precision. Discuss the relation in terms of stability and utility. Use the precision-recall graphs to support your points.
Lab 4: Query expansion

The purpose of this lab is to gain experience with query expansion algorithms. You must conduct experiments with initial document rankings created by i) your implemented algorithms, and ii) a reference baseline. You must conduct five experiments that investigate the sensitivity of pseudo relevance feedback algorithm to parameter settings and its effectiveness in different situations.

Linguistic query expansion

The intuitive way of expanding a query is to add terms to the query that synonyms of the original query terms. To implement this expansion method, one needs a dictionary to find word synonyms. WordNet is a lexical database of English and provides sets of synonyms. In Lucene, WordNet is available as WordnetSynonymParser and can be used to expand the query (expanding words at indexing time significantly increases the computational complexity and the require space to store the index).

Corpus-based query expansion

Pure linguistic terms expansion can be too generic to be useful in specific domains. For example, in programming, the technical jargon can be too specific to be expanded by a language standard synonyms. A better way to expand domain specific jargon with synonyms is to look at the co-occurrence of terms in the date.

A corpus based expansion can be implemented by searching a single query term at a time and counting the most common words in the top returned documents. Repeating this process for all query terms will give you a list of terms that co-occur frequently with your query terms. Thus, they can be used as to expand the query in the domain of that corpus.

Pseudo-relevance feedback

Relevance feedback is a manual procedure to expand the original query with terms from documents that the user mark as relevant. It builds on the possibility of doing interactive search where on each iteration the user adds more information to the original query.

Pseudo-relevance feedback simulates the user and automatically expands the original query with the most frequent terms of the top retrieved documents. The expanded query is resubmitted to the search engine and new results.

Implement a pseudo-relevance feedback query expansion algorithm. Use the top 10 documents as pseudo-relevant documents and consider the 10 most frequent words as expansion terms. Assume a weight of 1.0 on the original query terms and a weight of 0.5 on the expanded terms as follows:

```
"original query (expanded terms separated by space)"^0.5
```

Please read the full documentation regarding the query syntax. Compare the retrieval results with and without pseudo-relevance feedback.

---

3 This lab is an excerpt from: http://boston.lti.cs.cmu.edu/classes/11-642/HW/HW3/
Discussion

1. Compare the effects of setting the number of feedback documents to 1, 3, 5, 10, 20, 30, 40 and 50 on PRF query expansion accuracy and stability using the reference baseline results for the initial retrieval.

2. Use the best setting that you discovered in your previous experiment. Compare the effects of setting the number of feedback terms to 5, 10, 20, 30, 40, and 50 on PRF query expansion accuracy and stability using the reference baseline results for the initial retrieval.

3. Use the best settings that you discovered in your previous experiments. Consider the query expression: 
   \((\text{original query})^w \text{ (expanded terms separated by space)}^{(1-w)}\). Compare the effects of setting the weights as of the original terms to 0.0 (only expansion terms), 0.2, 0.4, 0.6, 0.8, and 1.0 (no query expansion) on query expansion accuracy and stability using the reference baseline results for the initial retrieval.

4. Implement a negative feedback where terms that are frequent bellow position 1000, should be used to filter out terms that are frequent at the top of the rank. Use the filtered topWords to expand the query. Discuss the obtained results.
Lab 5: Retrieval models

The purpose of this lab is to get familiar with the most popular retrieval models. Lucene’s search framework implements several retrieval models to compute the collection statistics and rank documents based on different fundaments. You should be able to relate the experimental results to the different foundations of each retrieval model.

Documents ranking with Lucene’s retrieval models

A central challenge to search engines is the retrieval model that computes a rank of documents based on a free text query provided by the end-user. Over the years many retrieval models have been researched, each one showing particular advantages in specific domains (e.g., medical domain, long-documents, short-documents, etc).

Lucene implements several retrieval models. Lucene’s API, allow changing the retrieval model both at indexing and search time:

- At indexing time, use the method: `IndexWriterConfig.setSimilarity(Similarity)`
- At search time, use the method: `IndexSearcher.setSimilarity(Similarity)`

By default, Lucene uses the BM25 retrieval model (however, this depends on the version).

Vector Space Model (Cosine TF-IDF)

The Vector Space Model (implemented as the `ClassicSimilarity`) is one of the most popular retrieval models. It weights the terms with the term frequency and with the inverse document frequency. The ranking is obtained with the cosine distance.

Best Model 25 (BM25)

The family of probabilistic retrieval models has a long history of successive improvements, until the mid 90’s when the Probabilistic Model BM25 was invented (implemented as `BM25Similarity`). There are many variations of the BM25 for different situations, however, the BM25 retrieval model is still the best model for a wide range of collections

\[
RSV = \sum q_t \cdot \frac{f_{t,d}(k_1 + 1)}{k_1 \left( (1 - b) + b \left( \frac{l_{avg}}{l_d} \right) \right) + f_{t,d}} \cdot IDF_t
\]

The variable \( k_1 \) controls term frequency scaling \((k_1 = 0 \text{ is binary model and } k_1 = 1 \text{ large is raw term frequency. The variable } b \text{ controls document length normalization (} b = 0 \text{ is no length normalization and } b = 1 \text{ is fully scaled by document length).})$

Language Model with Dirichlet Smoothing (LMD)

Language models estimate the term distribution of the collection and the terms distribution of each document. Retrieval models based on language models, combine the two distributions in different ways. The Language Model with Dirichlet Smoothing retrieval model (implemented in `LMDirichletSimilarity`), smooths the document terms distribution with a prior distribution corresponding to the collection’s terms distribution:

\[
p(q|d) = \prod_{t \in q} \left( \frac{f_{t,d} + \mu \cdot M_c(t)}{|d| + \mu} \right)^{q_t}
\]
The $\mu$ variable controls the smoothing effect, i.e., the deviation of the document’s terms distribution from a prior distribution (the collection terms distribution).

**Discussion**

1. Present the results of the studied retrieval models in a tabular format (ClassicSimilarity, BM25Similarity and LMDirichletSimilarity). Use the main retrieval metrics ($P@10$, MAP and NDCG). Plot the precision recall curves for all retrieval models. Discuss the results.

2. Using the setup of the previous question, compare the effects of different values of $\mu$ in the LMDirichletSimilarity (consider 10, 100, 500, 1000 and 5000). Discuss the results.

3. Using the setup of the previous question, compare the effects of setting different values to $b$ and $k_1$ in the BM25Similarity. Use $b\in\{0.0, 0.25, 0.5, 0.75, 1.0\}$ and $k_1\in\{0, 0.5, 1.0, 1.25, 1.5, 2.0\}$. Discuss the results.
Advanced discussion

4. Examine the document length per query and relate it to the performance of each retrieval model. Examine the collection statistics and relate it to the performance of the retrieval models. Discuss the ideal conditions for each retrieval model.

5. Implement a document weight decay function that penalizes older documents.

6. Consider the LMD retrieval model with PRF. Investigate the effects of PRF $\mu$ smoothing parameter on the retrieval accuracy of expanded queries. Generate three sets of expanded queries: $fbTerms=10$, $fbTerms=20$, and $fbTerms=30$. (You may use whatever values of $fbDocs$ you think is best, based on your previous experiments.) Compare the effects of the default $\mu=2500$ setting and five other values of $\mu$ on retrieval accuracy. Do the longer expanded queries require different smoothing than the shorter unexpanded queries?
Lab 6: Indexing multiple fields

In this lab you will compute several different statistics and retrieval models for the same set of document. You will also examine the advantages of having multiple ranks.

Creating a large set of indexing fields

Indexing documents across multiple fields is a fundamental functionality to index information according to their semantics (e.g., title, body, prices, names, locations). A problem arising from multi-field indexes is that you may wish to analyse the text of each field with different Analyzers.

Taking advantage of Lucene’s **analysers** and **retrieval models**, create multiple fields each one with the configurations listed below and with the analysers of your choice. Based on your observations of the previous labs, decide the configuration of the three last fields.

Once the index is created, you can query just one field, a few of them or even all fields and merge them onto a single rank. Lucene also supports querying multiple fields and computing a weighted average of the documents.

**The goal of this lab is to index the first paragraph and the full body of answers in separate fields using different analysers.**

PerField processing

Lucene provides the PerFieldAnalyzerWrapper classes to select the text analysis algorithms according to the field name. This example shows how we can build an analyser, aWrapper, that can later be passed to the IndexWriter or IndexWriterConfig:

```java
Map<String,Analyzer> analyzerPerField = new HashMap<>();
analyzerPerField.put("firstname", new KeywordAnalyzer());
analyzerPerField.put("lastname", new KeywordAnalyzer());
PerFieldAnalyzerWrapper aWrapper = new PerFieldAnalyzerWrapper(new StandardAnalyzer(), analyzerPerField);
```

Similarly, Lucene also provides the PerFieldSimilarityWrapper abstract class to select the retrieval model according to the field name. In this case, you must implement the actual class:

```java
class Lab7_RetrievalModels extends PerFieldSimilarityWrapper {
    @SuppressWarnings("deprecation")
    public Lab7_RetrievalModels() {
        similarityPerField.put("firstsentence", new LMDirichletSimilarity());
        similarityPerField.put("body", new BM25Similarity());
    }

    @Override
    public Similarity get(String s) {
        return similarityPerField.get(s);
    }
}
```

Query processing

This is an excerpt from Lucene's Documentation concerning the syntax to query multiple fields. Please read the full documentation regarding the query syntax.

Lucene supports fielded data. When performing a search you can either specify a field, or use the default field. The field names and default field is implementation specific. You can search any field by typing the field name followed by a colon ":" and then the term you are looking for.

As an example, let's assume a Lucene index contains two fields, title and text and text is the default field. If you want to find the document entitled "The Right Way" which contains the text "don't go this way", you can enter:

```
title:"The Right Way" AND text:go
```

or

```
title:"The Right Way" AND go
```

Since text is the default field, the field indicator is not required. Note: The field is only valid for the term that it directly precedes, so the query

```
title:The Right Way
```

Will only find "The" in the title field. It will find "Right" and "Way" in the default field (in this case the text field).
Discussion

1. Discuss the analysers used on each field. Explain the semantics and the rationale of each field.

2. Compare the performance of individual fields.

3. Compare the performance of the individual ranks (individual fields) to the performance of the ranks combined with a query expression.

4. Explain how Lucene combines the search results of the different fields. Suggest methods to improve it.
Lab 7: Rank fusion and learning to rank

In this lab you will study different methods to merge the outputs of different retrieval models and statistics related to individual documents. Merging different ranks, allows taking advantage of the different properties of each retrieval model. We will examine methods from two different areas: unsupervised rank fusion and supervised rank fusion methods.

Searching with multiple fields

There are two ways to search multiple fields with Lucene. The first method is with unsupervised rank fusion methods and the second method is with learning to rank methods.

The unsupervised fusion methods, require you to query all fields you need, collect all the documents and weighted them according to one of the methods.

The learning to rank methods is supported by the `MultiFieldQueryParser` class to search multiple fields. The learning to rank algorithms are responsible to learn the weight of each field in a weighted average fashion. Then, the constructor receives the set of boost that weight fields according to their importance:

```java
MultiFieldQueryParser(String[] fields, Analyzer analyzer, Map<String, Float> boosts)
```

Individual fields have their own analyser and possibly retrieval model. To generate the `Query object`, the query text must be processed by the same analyser used to index that field, and then passed to the `Similarity` model. Using the same `PerFieldAnalyser` that was used at indexing time, you can query multiple fields as follows:

```java
String[] query = {"query1", "query2", "query3"};
String[] fields = {"filename", "contents", "description"};
BooleanClause.Occur[] flags = {BooleanClause.Occur.SHOULD, BooleanClause.Occur.MUST,
                               BooleanClause.Occur.MUST_NOT};
MultiFieldQueryParser.parse(query, fields, flags, analyzer);
```

Unsupervised rank fusion

Unsupervised rank fusion methods are an inexpensive way of merging different ranks. When merging ranks, it is possible to consider the positions of a document on the multiple ranks or to consider the scores of documents on those same multiple ranks.

The reciprocal rank fusion weights each document with the inverse of its position on the rank, favouring documents at the “top” of the rank and penalizing documents below the “top” of the rank. This rank fusion method is expressed as

\[
RRFscore(d) = \sum_{i} \frac{1}{k + r_i(d)}.
\]
Instead of using just the position of the document on the list, other methods use the score of the document on the different lists. These include three rank fusion methods that use the maximum (CombMAX), minimum (CombMIN) or sum (CombSUM) of a document scores. The CombMNZ multiplies the number of ranks where the document occurs by the sum of the scores obtained across all lists. Despite normalization issues common in score-based methods, CombMNZ is competitive with rank-based approaches.

\[
\begin{align*}
\text{CombMAX}(d) &= \max\{s_0(d), \ldots, s_n(d)\} \\
\text{CombMIN}(d) &= \min\{s_0(d), \ldots, s_n(d)\} \\
\text{CombSUM}(d) &= \sum_i s_i(d) \\
\text{CombMNZ}(d) &= |\{i \mid d \in \text{Rank}_i\}| \cdot \sum_i s_i(d)
\end{align*}
\]

Using the indexes generated in the previous lab, implement a rank fusion class that queries the different fields and merges the outputs with the five above methods.

**Learning-to-rank (LETOR)**

The above methods ignore the performance of each individual rank, becoming vulnerable to noise that may exist in some rank. LETOR methods\(^4\) are a family of supervised methods that have an ordinal output. A key challenge in this task is that the objective function in information retrieval is not convex, such as the MAP or the P@10 metrics, resulting on a non-trivial optimization problem.

Despite the simplicity of linear models, when the objective function is considered on a multinomial manifold. The Coordinate Ascent algorithm can then be successfully applied to learn the weighted linear combination that maximizes MAP or another retrieval metric,

\[
R_SV(q, d) = \lambda_1 \cdot f_1(q, d) + \lambda_2 \cdot f_2(q, d) + \cdots + \lambda_n \cdot f_n(q, d),
\]

where for each query \(q\), \(f_i(q, d)\) corresponds to a position of the document \(d\) on the rank produced by the field \(i\). There may be an arbitrary number of fields/ranks.

**Model development.** Read the RankLib documentation and understand the format of the training files. Read your qrels.txt file and for each query-document pair, generate the scores for all features/fields of the indexes of the previous lab. Use this file to train a coordinate ascent model, optimising the MAP metric and store the model into a (human readable) file.

**Discussion**

1. **Apply the min-max normalization to the scores of the individual ranks.** Discuss the impact of normalization on the rank fusion. Does it exhibit the same change across all queries?

---

\(^4\) SVMRank is a LETOR model that makes use of maximum-margin theory to learn the ranking function. GBDT is one of the best models to solve LETOR problems.
2. Compare the results of the individual ranks to results of the studied rank fusion methods. Use the main retrieval metrics (P@10, MAP and NDCG) and plot the precision-recall curves for all fusion methods. How do the different methods compare in terms of these metrics? How different are the methods along the precision-recall curve? Discuss the results.

3. Change the regularization parameter (0.1, 0.2, 0.5, 1.0, 2.0) of the coordinate-ascent and present the new results.

4. List the field weights computed by the coordinate-ascent learning-to-rank method. Analyse the field weights on a per-query basis and discuss the performance differences. Compare the field weights to the performance of the individual ranks.
Lab 8: PageRank for the StackOverflow Social-Graph

Ranking with text only can lead to tied results, moreover, it ignores many other sources of evidence that can further improve the search results. On the Web (and in particular social-media), it is widely known that user feedback provides some of the best sources of evidence.

Google’s page rank is one of the first algorithms to use human relevance in the ranking of Web information. It relied on the links created by humans as a proxy to the question: “how relevant is this page on the whole Web?” The PageRank of a Web page $i$, is defined as

$$p_i = \frac{(1-d)}{N} + d \sum_{j=1}^{N} \left( \frac{L_{ij}}{c_j} \right) p_j$$

Where $d$ is the teleporting factor, $p_j$ is the PageRank of Web page $j$, $c_j$ is the number of out links of that page, and $L_{ij}$ indicates if there is a valid link from page $p_i$ to page $p_j$.

StackOverflow social-graph

In the StackOverflow dataset, human relevance is explicitly provided by the score given to an answer. We obviously don’t want to score the answers but the users instead, to predict the relevance of future answers published by that user, and thus, influence the ranking of the answers.

**PageRank**

In today’s lab, you will implement the PageRank algorithm based on the users’ feedback. You should create a graph of users where a set of Q&A will link sets of users. The steps to compute the PageRank for users are as follows:

- **Step 1**: Parse the Questions file, load the questions and identify the set of users.
- **Step 2a**: Parse the Answers file and link the Q-user and the A-user:
  - **Step 2b**: Decide which should be the direction of the link (Q->A or A->Q).
  - **Step 2c**: Store the full set of links grouped by user.
- **Step 3**: Initialize the PageRank of each user with a seed value of $1/\#\text{total users}$.
- **Step 4**: Iterate over the full set of links and update the PageRank of each user.
**PageRank with weighted links**

The link between a Question and an Answer is further qualified by the manual scores. Adapt your PageRank implementation to consider the manual score of Questions and Answers in the propagation of the PageRank value.

**Re-rank search results**

Run your PageRank implementation for 10 iterations and output the PageRank value of each user into a file. Implement a re-ranking method that computes the text-based search results and update its order with the users’ PageRank value. For each document, its PageRank and Lucene score should be weighted differently according to a parameter passed in your reranking method. This weight must be calibrated offline.

**Discussion**

1. Test the re-ranking method with different weights and plot the change in P@10. What is the best weight? Discuss the curve.

2. Plot the users PageRank versus the manual score of the user’s answers. Discuss the relation.

3. Plot the user’s PageRank versus the user’s number of answers/questions the user. Discuss the relation.

4. Discuss how PageRank, or other graph based methods, can be applied to other problems in Web and Social-media search.
Exercises
The following list of exercises are a selection of exercises from both textbooks and exercises from previous years' exams.

1. Are the following statements true or false?
   a. In a Boolean retrieval system, stemming never lowers precision.
   b. In a Boolean retrieval system, stemming never lowers recall.
   c. Stemming increases the size of the vocabulary.
   d. Stemming should be invoked at indexing time but not while processing a query.

2. Consider the tf-idf term weighting.
   a. What is the idf of a term that occurs in every document? Compare this with the use of stop word lists.
   b. Can the tf-idf weight of a term in a document exceed 1?

3. Assume a biword index. Give an example of a document which will be returned for a query of New York University but is actually a false positive which should not be returned.

<table>
<thead>
<tr>
<th></th>
<th>docFrequency</th>

<td>0</td>
<td>17</td>
</tr>
</tbody>
</table>

   a. Compute the tf-idf weights for the terms car, auto, insurance, best, for each document.
   b. Compute the rank of the three documents for the query “auto insurance” on the vector space model.
5. Consider a retrieval system with TF-IDF weighting and cosine ranking. The repository has a total of 1000 documents.
   a. Compute the similarity between the two documents.
      
      A: “This update is designed to reduce rankings for low-quality sites—sites which are low-value add for users, copy content from other websites or sites that are just not very useful.”
      
      B: “We can’t make a major improvement without affecting rankings for many sites. It has to be that some sites will go up and some will go down.”
      
      Source: http://googleblog.blogspot.com/2011/02/finding-more-high-quality-sites-in.html
   
   b. Which document is the most relevant for the query “ranking sites”?
   
   c. The TF-IDF weighting is composed by two parts. Explain the motivation for each part and detail how they are combined.

6. Suppose that a user’s initial query is “ranking sites”. The user examines two documents, A and B (the same from the previous question). She judges A, relevant and B nonrelevant. Assume that we are using direct term frequency (with no scaling and no document frequency). There is no need to length-normalize vectors.
   a. Using Rocchio relevance feedback what would the revised query vector be after relevance feedback? Assume $\alpha = 1$, $\beta = 0.75$, $\gamma = 0.25$.
   
   b. Discuss the limitations of the Rocchio algorithm.

7. Consider an indexing system implementing a specific postings structure including, the weight and the occurrence positions within the document.

   a. Propose a term weighting scheme and a ranking algorithm considering the occurrence position information.
   
   b. Modify the Block Sort-Based Indexing method to generate the above index structure with positional indexing.
8. Consider an information need for which there are 4 relevant documents in the collection. Contrast two systems run on this collection. Their top 15 results are judged for relevance as follows (the leftmost item is the top ranked search result):

<table>
<thead>
<tr>
<th>System 1</th>
<th>R N R N N N N R N N N N R</th>
</tr>
</thead>
<tbody>
<tr>
<td>System 2</td>
<td>N R N N R N N N N N N N N N</td>
</tr>
</tbody>
</table>

a. What is the MAP of each system? Which has a higher MAP?
b. Does this result intuitively make sense? What does it say about what is important in getting a good MAP score?
c. What is the Recall after 10 retrieved documents of each system?
d. Plot the precision-recall curve for both systems.

9. Below is a table showing how two human judges rated the relevance of a set of 12 documents to a particular information need (0 = nonrelevant, 1 = relevant). Let us assume that you’ve written an IR system that for this query returns the set of documents \( \{4, 5, 6, 7, 8\} \).

<table>

</tbody>
</table>

a. Calculate the kappa measure between the two judges.
b. Calculate precision, recall, and F1 of your system if a document is considered relevant only if the two judges agree.
c. Calculate precision, recall, and F1 of your system if a document is considered relevant if either judge thinks it is relevant.
10. Consider two ranking algorithms that for the same query produced the two following ranks:

\[ S1: d4 \ d3 \ d5 \ d8 \ d2 \quad \text{and} \quad S2: d3 \ d9 \ d5 \ d6 \ d1 \]

a. Assuming that the relevant documents are d9, d1, d3 and d4, compute the precision and recall values of each system.

b. Assuming that the multi-value relevance judgments of documents are d9=1, d1=1, d3=3 and d4=2, assess and compare the two ranks with the appropriate metric.

c. Assume no relevance judgments and compare the two systems.

11. Consider a search engine implementing a query categorization module and a topic-specific page rank algorithm. The query categories are: sports, news, health, navigational.

a. Propose a method to categorize queries. Consider the DMOZ directory.

b. Discuss in detail how the final rank is computed from the query categorization, the topic-specific PageRank and the document ranking modules.

12. Consider the two following documents:

\[ d1: \text{Jackson was one of the most talented entertainers of all time} \]
\[ d2: \text{Michael Jackson anointed himself King of Pop} \]

a. Using a BM25 retrieval model determine which document is more relevant to the query \( q= \text{“Michael Jackson”} \) (consider \( b = 0.75 \) and \( k = 1.5 \)).

b. Using a language model with Jelinek-Mercer smoothing determine which document is more relevant to the query \( q= \text{“Michael Jackson”} \) (consider \( \lambda = \frac{1}{2} \))

c. Using a language model with Dirichlet smoothing determine which document is more relevant to the query \( q= \text{“Michael Jackson”} \) (consider \( \mu = 100 \))

13. Considering the Probability Ranking Principle as a starting point, discuss the rationale behind the BM-25 model and the Language Model with Dirichlet Smoothing.

15. What are the differences between standard vector space TF-IDF weighting and the BIM probabilistic retrieval model (in the case where no document relevance information is available)?
16. Information Retrieval systems can implement several different weighting schemes and ranking functions.
   
a. Discuss the differences between the following term weighting functions: i) Binary; ii) frequency, and iii) tf-idf.

b. Discuss the differences between the following ranking functions: i) Euclidean distance, ii) cosine distance, and iii) BM25.

17. Show that models resulting from Dirichlet smoothing can be treated as probability distributions. That is, show that $\sum_{t} M^u_d(t) = 1$.

18. You have discovered that documents in a certain collection have a “half-life” of 30 days. After any 30-day period a document’s prior probability of relevance $p_r(D)$ is half of what it was at the start of the period. Incorporate this information into LMD. Simplify the equation into a rank-equivalent form, making any assumptions you believe reasonable.

19. Let $X_t$ be a random variable indicating whether the term $t$ appears in a document. Suppose we have $|R|$ relevant documents in the document collection and that $X_t = 1$ in $s$ of the documents. Take the observed data to be just these observations of $X_t$ for each document in $R$. Show that the MLE for the parameter $p_t = P(X_t = 1 | R = 1, \sim q)$, that is, the value for $p_t$ which maximizes the probability of the observed data, is $p_t = \frac{s}{|R|}$.

20. Consider making a language model from the following training text:

   the martian has landed on the latin pop sensation ricky martin

a. Under a MLE-estimated unigram probability model, what are $P(\text{the})$ and $P(\text{martian})$?

b. Under a MLE-estimated bigram model, what are $P(\text{sensation} | \text{pop})$ and $P(\text{pop} | \text{the})$?

21. Consider a search engine implementing a query categorization module and a topic-specific page rank algorithm. The query categories are: sports, news, health, navigational.

   a. Propose a method to categorize queries. Consider the HITS system.

   b. Discuss how the topic-specific PageRank is implemented.
22. Suppose we have a collection that consists of the 4 documents given in the below table.

<table>
<thead>
<tr>
<th>docID</th>
<th>Document text</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>click go the shears boys click click click</td>
</tr>
<tr>
<td>2</td>
<td>click click</td>
</tr>
<tr>
<td>3</td>
<td>metal here</td>
</tr>
<tr>
<td>4</td>
<td>metal shears click here</td>
</tr>
</tbody>
</table>

Build a query likelihood language model for this document collection. Assume a mixture model between the documents and the collection, with both weighted at 0.5. Maximum likelihood estimation (mle) is used to estimate both as unigram models.

a. Work out the model probabilities of the queries “click”, “shears”, and hence “click shears” for each document, and use those probabilities to rank the documents returned by each query.

b. What is the final ranking of the documents for the query click shears?

23. Using the calculations in Exercise 17 as inspiration or as examples where appropriate, write one sentence each describing the treatment that the LM with Jelinek-Mercer smoothing gives to each of the following quantities. Include whether it is present in the model or not and whether the effect is raw or scaled.

a. Term frequency in a document
b. Collection frequency of a term
c. Document frequency of a term
d. Length normalization of a term

24. In the mixture model approach to the query likelihood model,

\[
p(q|d, C) \approx \prod_{t \in [q \cap d]} (\lambda \cdot p(t|M_d) + (1 - \lambda) \cdot p(t|M_C)),
\]

the probability estimate of a term is based on the term frequency of a word in a document, and the collection frequency of the word. Doing this certainly guarantees that each term of a query (in the vocabulary) has a non-zero chance of being generated by each document. But it has a more subtle but important effect of implementing a form of term weighting, related to TF-IDF that was discuss in (Manning et al., Chapter 6). Explain how this works. In particular, include in your answer a concrete numeric example showing this term weighting at work.

25. Consider the PageRank algorithm applied to a term graph.

a. Propose an algorithm to compute the term graph from a set of documents (consider LSI and simple term co-occurrence).

b. Discuss possible ways in which the PageRank algorithm can be used to compute the importance of a term.
   a. Compute the PageRank of each page on the following Web graph.
      Consider PR(A) = 0.2 and a teleporting factor of 0.3.
   b. Explain how PageRank can be adapted to user preferences. (Assume preferences are expressed by categories of content).
   c. In the PageRank algorithm what is the teleporting factor and why is it needed?
   d. Compute the HITS algorithm for the above Web graph.

27. Rank fusion methods combine ranks in different manners. Compute the fused ranks for the following three lists with the CombSUM, CombMNZ, BordaFuse and RRF.

<table>
<thead>
<tr>
<th>Rank 1 (id/score)</th>
<th>Rank 2 (id/score)</th>
<th>Rank 3 (id/score)</th>
</tr>
